#### State of the Art

Alzheimer's Disease (AD) is a degenerative brain disorder characterized clinically by progressive loss of memory, cognition, reasoning, judgment and emotional stability that gradually leads to profound mental deterioration and ultimately death. AD is a very common cause of progressive mental failure (dementia) in aged humans and is believed to represent the fourth most common medical cause of death in the United States. AD has been observed in races and ethnic groups worldwide and presents a major present and future public health problem. The disease is currently estimated to affect about two to three

40

-- 4 --

million individuals in the United States alone. AD is at present incurable. No treatment that effectively prevents AD or reverses its symptoms and course is currently known.

5           The brains of individuals with AD exhibit characteristic lesions termed senile (or amyloid) plaques, amyloid angiopathy (amyloid deposits in blood vessels) and neurofibrillary tangles. Large numbers of these lesions, particularly amyloid plaques and neurofibrillary tangles, are generally found in several areas of the human brain important for memory and cognitive function  
10       in patients with AD. Smaller numbers of these lesions in a more restrictive anatomical distribution are also found in the brains of most aged humans who do not have clinical AD. Amyloid plaques and amyloid angiopathy also characterize the brains of individuals with Trisomy 21 (Down's Syndrome) and Hereditary Cerebral Hemorrhage with Amyloidosis of the Dutch Type  
15       (HCHWA-D). At present, a definitive diagnosis of AD usually requires observing the aforementioned lesions in the brain tissue of patients who have died with the disease or, rarely, in small biopsied samples of brain tissue taken during an invasive neurosurgical procedure.

20           The principal chemical constituent of the amyloid plaques and vascular amyloid deposits (amyloid angiopathy) characteristic of AD and the other disorders mentioned above is an approximately 4.2 kilodalton (kD) protein of about 39-43 amino acids designated the  $\beta$ -amyloid peptide ( $\beta$ AP) or sometimes  $A\beta$ ,  $A\beta P$  or  $\beta/A4$ .  $\beta$ -Amyloid peptide was first purified and a partial amino  
25       acid sequence was provided by Glenner, et al.<sup>1</sup> The isolation procedure and the sequence data for the first 28 amino acids are described in U.S. Patent No. 4,666,829<sup>2</sup>.

          Molecular biological and protein chemical analyses have shown that the  
30        $\beta$ -amyloid peptide is a small fragment of a much larger precursor protein (APP), that is normally produced by cells in many tissues of various animals,

-- 5 --

including humans. Knowledge of the structure of the gene encoding the APP has demonstrated that  $\beta$ -amyloid peptide arises as a peptide fragment that is cleaved from APP by protease enzyme(s). The precise biochemical mechanism by which the  $\beta$ -amyloid peptide fragment is cleaved from APP and subsequently deposited as amyloid plaques in the cerebral tissue and in the walls of the cerebral and meningeal blood vessels is currently unknown.

Several lines of evidence indicate that progressive cerebral deposition of  $\beta$ -amyloid peptide plays a seminal role in the pathogenesis of AD and can precede cognitive symptoms by years or decades. See, for example, Selkoe<sup>3</sup>. The most important line of evidence is the discovery that missense DNA mutations at amino acid 717 of the 770-amino acid isoform of APP can be found in affected members but not unaffected members of several families with a genetically determined (familial) form of AD (Goate, et al.<sup>4</sup>; Chartier-Harlan, et al.<sup>5</sup>; and Murrell, et al.<sup>6</sup>) and is referred to as the Swedish variant. A double mutation changing lysine<sup>595</sup>-methionine<sup>596</sup> to asparagine<sup>595</sup>-leucine<sup>596</sup> (with reference to the 695 isoform) found in a Swedish family was reported in 1992 (Mullan, et al.<sup>7</sup>). Genetic linkage analyses have demonstrated that these mutations, as well as certain other mutations in the APP gene, are the specific molecular cause of AD in the affected members of such families. In addition, a mutation at amino acid 693 of the 770-amino acid isoform of APP has been identified as the cause of the  $\beta$ -amyloid peptide deposition disease, HCHWA-D, and a change from alanine to glycine at amino acid 692 appears to cause a phenotype that resembles AD in some patients but HCHWA-D in others. The discovery of these and other mutations in APP in genetically based cases of AD prove that alteration of APP and subsequent deposition of its  $\beta$ -amyloid peptide fragment can cause AD.

Despite the progress which has been made in understanding the underlying mechanisms of AD and other  $\beta$ -amyloid peptide related diseases, there remains a need to develop methods and compositions for treatment of the

-- 6 --

disease(s). Ideally, the treatment methods would advantageously be based on drugs which are capable of inhibiting  $\beta$ -amyloid peptide release and/or its synthesis *in vivo*.

5

-- 76 --

Compound Preparation

The compounds of formula I are readily prepared via several divergent synthetic routes with the particular route selected relative to the ease of compound preparation, commercial availability of starting materials, etc.

- 5           A first synthetic method involves conventional coupling of an acetic acid derivative with a primary amine of an esterified amino acid as shown in reaction (1) below:

wherein  $\text{R}^1$ ,  $\text{R}^2$ ,  $\text{R}^3$ ,  $\text{X}'$  and  $\text{X}''$  are as defined above, and  $\text{X}$  is either oxygen or -NH-.

- 25           Reaction (1) merely involves coupling of a suitable acid derivative 1 with the primary amine of amino acid ester 2 under conditions which provide for the N-acetyl derivative 3. This reaction is conventionally conducted for

-- 77 --

peptide synthesis and synthetic methods used therein can also be employed to prepare the N-acetyl amino acid esters **3** of this invention. For example, well known coupling reagents such as carbodiimides with or without the use of well known additives such as N-hydroxysuccinimide, 1-hydroxybenzotriazole, etc.

5 can be used to facilitate coupling. The reaction is conventionally conducted in an inert aprotic diluent such as dimethylformamide, dichloromethane, chloroform, acetonitrile, tetrahydrofuran and the like. Alternatively, the acid halide of compound **1** can be employed in reaction (1) and, when so employed, it is typically employed in the presence of a suitable base to scavenge the acid

10 generated during the reaction. Suitable bases include, by way of example, triethylamine, diisopropylethylamine, N-methylmorpholine and the like.

Reaction (1) is preferably conducted at from about 0°C to about 60°C until reaction completion which typically occurs within 1 to about 24 hours. Upon reaction completion, N-acetyl amino acid ester **3** is recovered by

15 conventional methods including precipitation, chromatography, filtration and the like or alternatively is hydrolyzed to the corresponding acid without purification and/or isolation other than conventional work-up (e.g., aqueous extraction, etc.). Alternatively, the synthesis described above in reaction (1) can be conducted on the amino acid ( $XR^3 = OH$ ) and subsequent to N-acetyl formation

20 as described above.

In any event, if an N-acetyl amino acid ester is formed, it is converted to the corresponding acid prior to the coupling step with another amino acid ester/amide,  $HNR^3CR^4R^5C(O)Y$ . Coupling is accomplished using well known peptide coupling chemistry with well known coupling reagents such as

25 carbodiimides with or without the use of well known additives such as N-hydroxysuccinimide, 1-hydroxybenzotriazole, etc. which can be used to facilitate coupling. The reaction is conventionally conducted in an inert aprotic polar diluent such as dimethylformamide, dichloromethane, chloroform, acetonitrile, tetrahydrofuran and the like.

-- 78 --

Such coupling yields compounds of formula I where  $n$  is 1. The synthesis of compounds of formula I where  $n$  is 2 is accomplished via a second coupling reaction. Specifically, in the first coupling reaction,  $\text{HNR}^3\text{CR}^4\text{R}^5\text{C}(\text{O})\text{Y}$  is selected to be an amino acid ester. That is to say that Y is -O-alkyl. After coupling, the ester is hydrolyzed via conventional conditions well known in the art to provide for the corresponding carboxylic acid which can now be used to couple a second amino acid ester/amide.

In reaction (1), each of the reagents (compound 1 and amino acid ester 2) are well known in the art with a plurality of each being commercially available.

Alternatively, the compounds of formula I can be prepared by first forming the dipeptide ester and then N-acylating these esters. That is to say that the amino acid ester or amide  $\text{HNR}^3\text{CR}^4\text{R}^5\text{C}(\text{O})\text{Y}$  is coupled to the N-blocked amino acid  $\text{BlockNHCHR}^2\text{COOH}$  via conventional coupling conditions to provide for the dipeptide  $\text{BlockNHCHR}^2\text{C}(\text{O})\text{N}(\text{R}^3)\text{CR}^4\text{R}^5\text{C}(\text{O})\text{Y}$ . The blocking group is then removed via conventional conditions to provide for the free amine which is then N-acylated in the manner described above to provide for the compounds of formula I.

After coupling and N-acylation (in whatever order) is complete, the resulting esters and amides can be derivatized via conventional chemistry to provide for derivatives of the synthesized compounds. For example, conventional reduction of a terminal ester group with lithium borohydride leads to the terminal  $-\text{CH}_2\text{OH}$  group. Alternatively, an ester group can be converted to a primary amide  $[-\text{C}(\text{O})\text{NH}_2]$  by reaction with ammonia in methanol with a catalytic amount of sodium cyanide while heating.

Similarly, reactive functionality which is blocked on either  $\text{R}^2$  and/or  $\text{R}^3$  groups can be deblocked and then derivatized. For example, the a BOC

-- 79 --

protected amino group on R<sup>3</sup> (e.g., lysine side chain) can be deblocked after synthesis and the amino group acylated or otherwise derivatized.

Additionally, a terminal ester can be subjected to transesterification techniques to provide for other esters. Numerous techniques are known in the art to effect transesterification and each technique merely replaces one ester group with a different ester group derived from the corresponding alcohol or thioalcohol and, in some cases, a catalyst such as titanium (IV) *iso*-propoxide is used to facilitate reaction completion. In one technique, the alcohol or thioalcohol is first treated with sodium hydride in a suitable diluent such as toluene to form the corresponding sodium alkoxide or thioalkoxide which is then employed to effect transesterification. The efficiency of this technique makes it particularly useful with high boiling and/or expensive alcohols or thioalcohols.

In another transesterification technique, the ester to be transesterified is placed in a large excess of the alcohol or thioalcohol which effects transesterification. A catalytic amount of sodium hydride is then added and the reaction proceeds quickly under conventional conditions to provide the desired transesterified product. Because this protocol requires the use of a large excess of alcohol or thioalcohol, this procedure is particularly useful when the alcohol or thioalcohol is inexpensive.

Transesterification provides a facile means to provide for a multiplicity of different ester substituents on the compounds of formula I above. In all cases, the alcohols and thioalcohols employed to effect transesterification are well known in the art with a significant number being commercially available.

Other methods for preparing the esters of this invention include, by way of example, first hydrolyzing the ester to the free acid followed by O-alkylation with a halo-R<sup>3</sup> group in the presence of a base such as potassium carbonate.

-- 80 --

Alternatively, for esterification procedures for alcohols containing an ester group can be achieved by using the methods of Losse, et al.<sup>11</sup>

The compounds described herein can also be prepared by use of polymer supported forms of carbodiimide peptide coupling reagents. A polymer supported form of EDC, for example, has been described (*Tetrahedron Letters*, 34(48), 7685 (1993))<sup>10</sup>. Additionally, a new carbodiimide coupling reagent, PEPC, and its corresponding polymer supported forms have been discovered and are very useful for the preparation of the compounds of the present invention.

10 Polymers suitable for use in making a polymer supported coupling reagent are either commercially available or may be prepared by methods well known to the artisan skilled in the polymer arts. A suitable polymer must possess pendant sidechains bearing moieties reactive with the terminal amine of the carbodiimide. Such reactive moieties include chloro, bromo, iodo and  
15 methanesulfonyl. Preferably, the reactive moiety is a chloromethyl group. Additionally, the polymer's backbone must be inert to both the carbodiimide and reaction conditions under which the ultimate polymer bound coupling reagents will be used.

Certain hydroxymethylated resins may be converted into  
20 chloromethylated resins useful for the preparation of polymer supported coupling reagents. Examples of these hydroxylated resins include the 4-hydroxymethyl-phenylacetamidomethyl resin (Pam Resin) and 4-benzyloxybenzyl alcohol resin (Wang Resin) available from Advanced Chemtech of Louisville, Kentucky, USA (see Advanced Chemtech 1993-1994  
25 catalog, page 115). The hydroxymethyl groups of these resins may be converted into the desired chloromethyl groups by any of a number of methods well known to the skilled artisan.

-- 81 --

Preferred resins are the chloromethylated styrene/divinylbenzene resins because of their ready commercial availability. As the name suggests, these resins are already chloromethylated and require no chemical modification prior to use. These resins are commercially known as Merrifield's resins and are

5 available from Aldrich Chemical Company of Milwaukee, Wisconsin, USA (see Aldrich 1994-1995 catalog, page 899). Methods for the preparation of PEPC and its polymer supported forms are outlined in the following scheme.

Such methods are described more fully in U.S. Patent Application Serial No. 60/019,790 filed June 14, 1996 which application is incorporated herein by

10 reference in its entirety. Briefly, PEPC is prepared by first reacting ethyl isocyanate with 1-(3-aminopropyl)pyrrolidine. The resulting urea is treated with 4-toluenesulfonyl chloride to provide PEPC. The polymer supported form is prepared by reaction of PEPC with an appropriate resin under standard conditions to give the desired reagent.

-- 82 --

The carboxylic acid coupling reactions employing these reagents are performed at about ambient temperature to about 45°C, for from about 3 to 120 hours. Typically, the product may be isolated by washing the reaction with CHCl<sub>3</sub> and concentrating the remaining organics under reduced pressure. As  
5 discussed *supra*, isolation of products from reactions where a polymer bound reagent has been used is greatly simplified, requiring only filtration of the reaction mixture and then concentration of the filtrate under reduced pressure.

Still other methods for the preparation of esters are provided in the examples below.

10 Compounds where X is -CR<sup>6</sup>R<sup>6</sup>Y' are readily prepared by coupling, e.g., an amino alcohol H<sub>2</sub>NCR<sup>4</sup>R<sup>5</sup>CR<sup>6</sup>R<sup>6</sup>OH, to the carboxyl group of R<sup>1</sup>ZCX'X''C(O)NHCHR<sup>2</sup>C(O)OH under standard coupling conditions well known in peptide coupling chemistry which can use well known coupling  
15 reagents such as carbodiimides with or without the use of well known additives such as N-hydroxysuccinimide, 1-hydroxybenzotriazole, etc. If necessary, well known blocking groups on Y' can be employed to protect the group during coupling. Such blocking groups are particularly desirable when Y' is an amino group.

20 The reaction is conventionally conducted in an inert aprotic polar diluent such as dimethylformamide, dichloromethane, chloroform, acetonitrile, tetrahydrofuran and the like. Upon reaction completion, any blocking groups on Y' are selectively removed to provide for the desired compound.

When Y' is -OH or -SH, post-synthetic conversion of these groups to the corresponding esters (i.e., -OC(O)R<sup>7</sup>), disulfides (i.e., -SSR<sup>7</sup>) and  
25 -SSC(O)R<sup>7</sup> groups is accomplished using well known chemistry. For example, ester synthesis requires only reaction with a suitable acid such as acetic acid (R<sup>7</sup>

-- 83 --

= methyl), acid halide (e.g., acid chloride) or acid anhydride under suitable esterification conditions.

When one of R<sup>6</sup> is hydrogen, post-synthetic oxidation of the -CHR<sup>6</sup>OH group leads to the ketone derivatives. Alternatively, such ketones  
5 can be prepared by coupling the suitable aminoketone HCl salt with the terminal carboxyl group of the amino acid as illustrated in Example 168 below.

In these synthetic methods, the starting materials can contain a chiral center (e.g., alanine) and, when a racemic starting material is employed, the resulting product is a mixture of R,S enantiomers. Alternatively, a chiral isomer  
10 of the starting material can be employed and, if the reaction protocol employed does not racemize this starting material, a chiral product is obtained. Such reaction protocols can involve inversion of the chiral center during synthesis.

Accordingly, unless otherwise indicated, the products of this invention are a mixture of R,S enantiomers or diastereomers. Preferably, however, when a  
15 chiral product is desired, the chiral product corresponds to the L-amino acid derivative. Alternatively, chiral products can be obtained via purification techniques which separate enantiomers from a R,S mixture to provide for one or the other stereoisomer. Such techniques are well known in the art.

## 20 Pharmaceutical Formulations

When employed as pharmaceuticals, the compounds of formula I are usually administered in the form of pharmaceutical compositions. These compounds can be administered by a variety of routes including oral, rectal, transdermal, subcutaneous, intravenous, intramuscular, and intranasal. These  
25 compounds are effective as both injectable and oral compositions. Such compositions are prepared in a manner well known in the pharmaceutical art and comprise at least one active compound.

-- 84 --

This invention also includes pharmaceutical compositions which contain, as the active ingredient, one or more of the compounds of formula I above associated with pharmaceutically acceptable carriers. In making the compositions of this invention, the active ingredient is usually mixed with an excipient, diluted by an excipient or enclosed within such a carrier which can be in the form of a capsule, sachet, paper or other container. When the excipient serves as a diluent, it can be a solid, semi-solid, or liquid material, which acts as a vehicle, carrier or medium for the active ingredient. Thus, the compositions can be in the form of tablets, pills, powders, lozenges, sachets, cachets, elixirs, suspensions, emulsions, solutions, syrups, aerosols (as a solid or in a liquid medium), ointments containing, for example, up to 10% by weight of the active compound, soft and hard gelatin capsules, suppositories, sterile injectable solutions, and sterile packaged powders.

In preparing a formulation, it may be necessary to mill the active compound to provide the appropriate particle size prior to combining with the other ingredients. If the active compound is substantially insoluble, it ordinarily is milled to a particle size of less than 200 mesh. If the active compound is substantially water soluble, the particle size is normally adjusted by milling to provide a substantially uniform distribution in the formulation, e.g. about 40 mesh.

Some examples of suitable excipients include lactose, dextrose, sucrose, sorbitol, mannitol, starches, gum acacia, calcium phosphate, alginates, tragacanth, gelatin, calcium silicate, microcrystalline cellulose, polyvinylpyrrolidone, cellulose, sterile water, syrup, and methyl cellulose. The formulations can additionally include: lubricating agents such as talc, magnesium stearate, and mineral oil; wetting agents; emulsifying and suspending agents; preserving agents such as methyl- and propylhydroxybenzoates; sweetening agents; and flavoring agents. The compositions of the invention can be formulated so as to provide quick, sustained or delayed release

-- 85 --

of the active ingredient after administration to the patient by employing procedures known in the art.

The compositions are preferably formulated in a unit dosage form, each dosage containing from about 5 to about 100 mg, more usually about 10 to about 30 mg, of the active ingredient. The term "unit dosage forms" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with a suitable pharmaceutical excipient. Preferably, the compound of formula I above is employed at no more than about 20 weight percent of the pharmaceutical composition, more preferably no more than about 15 weight percent, with the balance being pharmaceutically inert carrier(s).

The active compound is effective over a wide dosage range and is generally administered in a pharmaceutically effective amount. It, will be understood, however, that the amount of the compound actually administered will be determined by a physician, in the light of the relevant circumstances, including the condition to be treated, the chosen route of administration, the actual compound administered, the age, weight, and response of the individual patient, the severity of the patient's symptoms, and the like.

For preparing solid compositions such as tablets, the principal active ingredient is mixed with a pharmaceutical excipient to form a solid preformulation composition containing a homogeneous mixture of a compound of the present invention. When referring to these preformulation compositions as homogeneous, it is meant that the active ingredient is dispersed evenly throughout the composition so that the composition may be readily subdivided into equally effective unit dosage forms such as tablets, pills and capsules. This solid preformulation is then subdivided into unit dosage forms of the type

-- 86 --

described above containing from, for example, 0.1 to about 500 mg of the active ingredient of the present invention.

The tablets or pills of the present invention may be coated or otherwise compounded to provide a dosage form affording the advantage of prolonged  
5 action. For example, the tablet or pill can comprise an inner dosage and an outer dosage component, the latter being in the form of an envelope over the former. The two components can be separated by an enteric layer which serves to resist disintegration in the stomach and permit the inner component to pass intact into the duodenum or to be delayed in release. A variety of materials can  
10 be used for such enteric layers or coatings, such materials including a number of polymeric acids and mixtures of polymeric acids with such materials as shellac, cetyl alcohol, and cellulose acetate.

The liquid forms in which the novel compositions of the present invention may be incorporated for administration orally or by injection include  
15 aqueous solutions suitably flavored syrups, aqueous or oil suspensions, and flavored emulsions with edible oils such as cottonseed oil, sesame oil, coconut oil, or peanut oil, as well as elixirs and similar pharmaceutical vehicles.

Compositions for inhalation or insufflation include solutions and suspensions in pharmaceutically acceptable, aqueous or organic solvents, or  
20 mixtures thereof, and powders. The liquid or solid compositions may contain suitable pharmaceutically acceptable excipients as described *supra*. Preferably the compositions are administered by the oral or nasal respiratory route for local or systemic effect. Compositions in preferably pharmaceutically acceptable solvents may be nebulized by use of inert gases. Nebulized solutions  
25 may be breathed directly from the nebulizing device or the nebulizing device may be attached to a face mask tent, or intermittent positive pressure breathing machine. Solution, suspension, or powder compositions may be administered,

-- 87 --

preferably orally or nasally, from devices which deliver the formulation in an appropriate manner.

15 Another preferred formulation employed in the methods of the present invention employs transdermal delivery devices ("patches"). Such transdermal patches may be used to provide continuous or discontinuous infusion of the compounds of the present invention in controlled amounts. The construction and use of transdermal patches for the delivery of pharmaceutical agents is well known in the art. See, e.g., U.S. Patent 5,023,252, issued June 11, 1991, herein incorporated by reference. Such patches may be constructed for continuous, pulsatile, or on demand delivery of pharmaceutical agents.

20 Frequently, it will be desirable or necessary to introduce the pharmaceutical composition to the brain, either directly or indirectly. Direct techniques usually involve placement of a drug delivery catheter into the host's ventricular system to bypass the blood-brain barrier. One such implantable delivery system used for the transport of biological factors to specific anatomical regions of the body is described in U.S. Patent 5,011,472 which is herein incorporated by reference.

Indirect techniques, which are generally preferred, usually involve formulating the compositions to provide for drug latentiation by the conversion

-- 92 --

of hydrophilic drugs into lipid-soluble drugs. Latentiation is generally achieved through blocking of the hydroxy, carbonyl, sulfate, and primary amine groups present on the drug to render the drug more lipid soluble and amenable to transportation across the blood-brain barrier. Alternatively, the delivery of hydrophilic drugs may be enhanced by intra-arterial infusion of hypertonic solutions which can transiently open the blood-brain barrier.

Other suitable formulations for use in the present invention can be found in *Remington's Pharmaceutical Sciences*, Mace Publishing Company, Philadelphia, PA, 17th ed. (1985).

#### 10 Utility

The compounds and pharmaceutical compositions of the invention are useful in inhibiting  $\beta$ -amyloid peptide release and/or its synthesis, and, accordingly, have utility in treating Alzheimer's disease in mammals including humans.

15 As noted above, the compounds described herein are suitable for use in a variety of drug delivery systems described above. Additionally, in order to enhance the *in vivo* serum half-life of the administered compound, the compounds may be encapsulated, introduced into the lumen of liposomes, prepared as a colloid, or other conventional techniques may be employed which provide an extended serum half-life of the compounds. A variety of methods are available for preparing liposomes, as described in, e.g., Szoka, et al., U.S. Patent Nos. 4,235,871, 4,501,728 and 4,837,028 each of which is incorporated herein by reference.

25 The amount of compound administered to the patient will vary depending upon what is being administered, the purpose of the administration, such as prophylaxis or therapy, the state of the patient, the manner of administration, and the like. In therapeutic applications, compositions are administered to a

-- 93 --

patient already suffering from AD in an amount sufficient to at least partially arrest further onset of the symptoms of the disease and its complications. An amount adequate to accomplish this is defined as "therapeutically effective dose." Amounts effective for this use will depend on the judgment of the attending clinician depending upon factors such as the degree or severity of AD in the patient, the age, weight and general condition of the patient, and the like. Preferably, for use as therapeutics, the compounds described herein are administered at dosages ranging from about 1 to about 500 mg/kg/day.

In prophylactic applications, compositions are administered to a patient at risk of developing AD (determined for example by genetic screening or familial trait) in an amount sufficient to inhibit the onset of symptoms of the disease. An amount adequate to accomplish this is defined as "prophylactically effective dose." Amounts effective for this use will depend on the judgment of the attending clinician depending upon factors such as the age, weight and general condition of the patient, and the like. Preferably, for use as prophylactics, the compounds described herein are administered at dosages ranging from about 1 to about 500 mg/kg/day.

As noted above, the compounds administered to a patient are in the form of pharmaceutical compositions described above. These compositions may be sterilized by conventional sterilization techniques, or may be sterile filtered. The resulting aqueous solutions may be packaged for use as is, or lyophilized, the lyophilized preparation being combined with a sterile aqueous carrier prior to administration. The pH of the compound preparations typically will be between 3 and 11, more preferably from 5 to 9 and most preferably from 7 and 8. It will be understood that use of certain of the foregoing excipients, carriers, or stabilizers will result in the formation of pharmaceutical salts.

The following synthetic and biological examples are offered to illustrate this invention and are not to be construed in any way as limiting the scope of

this invention. Unless otherwise stated, all temperatures are in degrees Celsius.

Coupling of  $R^1C(X')(X'')C(O)OH$  with  $H_2NCH(R^2)C(O)XR^3$ 

A solution of the acid (3.3 mmol) and CDI in 20 mL THF was stirred for 2 h. L-alanine *iso*-butyl ester hydrochloride (from Example B below) (3.6 mmol) was added, followed by 1.5 mL (10.8 mmol) of triethylamine. The reaction mixture was stirred overnight. The reaction mixture was diluted with 100 mL of diethyl ether, washed with 10% HCl three times, brine once, 20% potassium carbonate once and brine once. The solution was dried over magnesium sulfate, filtered, and evaporated at reduced pressure to yield the product. Other amino acid esters may also be employed in this procedure.

## GENERAL PROCEDURE C'

Esterification of  $R^1C(X')(X'')C(O)NHCH(R^2)C(O)OH$  With  $HOR^3$ 

To a stirred solution of phenylacetylvaline (1.6470 g, 7.0 mmol) in 20 mL THF was added CDI (1.05 g, 6.5 mmol) and the mixture was stirred for 1.5 h. 2-Methylbutanol (0.53 g, 6 mmol) was added the mixture, followed by addition of NaH (0.16 g, 6.5 mmol). Bubbling occurred immediately. The reaction mixture was stirred overnight. The reaction mixture was diluted with 100 mL of diethyl ether, washed with 10% HCl three times, brine once, 20% potassium carbonate once and brine once. The solution was dried over magnesium sulfate, filtered, and evaporated at reduced pressure to yield the product. Other N-acyl amino acids and alcohols may also be employed in this procedure.

## GENERAL PROCEDURE D'

Ester Hydrolysis to the Free Acid

Ester hydrolysis to the free acid was conducted by conventional methods. Below are two examples of such conventional de-esterification methods.

To the ester in a 1:1 mixture of  $CH_3OH/H_2O$  was added 2-5 equivalents of  $K_2CO_3$ . The mixture was heated to about 50°C for about 0.5 to 1.5 hours until tlc showed complete reaction. The reaction was cooled to room temperature

-- 98 --

and the methanol was removed at reduced pressure. The pH of the remaining aqueous solution was adjusted to about 2, and ethyl acetate was added to extract the product. The organic phase was then washed with saturated aqueous NaCl and dried over  $\text{MgSO}_4$ . The solution was stripped free of solvent at reduced pressure to yield the product.

The amino acid ester was dissolved in dioxane/water (4:1) to which was added LiOH (~2 eq.) that was dissolved in water such that the total solvent after addition was about 2:1 dioxane:water. The reaction mixture was stirred until reaction completion and the dioxane was removed under reduced pressure. The residue was diluted with EtOAc, the layers were separated and the aqueous layer acidified to pH 2. The aqueous layer was back extracted with EtOAc, the combined organics were dried over  $\text{Na}_2\text{SO}_4$  and the solvent was removed under reduced pressure after filtration. The residue was purified by conventional methods (e.g., recrystallization).

The following exemplifies this later example. The methyl ester of 3- $\text{NO}_2$  phenylacetyl alanine 9.27 g (0.0348 mols) was dissolved in 60 mL dioxane and 15 mL of  $\text{H}_2\text{O}$  and adding LiOH (3.06 g, 0.0731 mol) that has been dissolved in 15 mL of  $\text{H}_2\text{O}$ . After stirring for 4 hours, the dioxane was removed under reduced pressure and the residue diluted with EtOAc, the layers were separated and the aqueous layer acidified to pH 2. The aqueous layer was back extracted with EtOAc (4 X 100 mL), the combined organics were dried over  $\text{Na}_2\text{SO}_4$  and the solvent was removed under reduced pressure after filtration. The residue was recrystallized from EtOAc/isooctane giving 7.5 g (85%) of 3-nitrophenylacetyl alanine.  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{O}_5$  requires C = 52.38, H = 4.80, and N = 11.11. Analysis found C = 52.54, H = 4.85, and N = 11.08.  $[\alpha]_{25} = -29.9 @ 589 \text{ nm}$ .

## GENERAL PROCEDURE E'

Low Temperature BOP Coupling of Acid and Alcohol

A solution of methylene chloride containing the carboxylic acid (100M%) and N-methyl morpholine (150 M%) was cooled to -20°C under nitrogen.

- 5 BOP (105 M%) was added in one portion and the reaction mixture was maintained at -20°C for 15 minutes. The corresponding alcohol (120 M%) was added and the reaction mixture was allowed to warm to room temperature and stirred for 12 hours. The reaction mixture was then poured into water and extracted with ethyl acetate (3x). The combined ethyl acetate portions were  
10 backwashed with saturated aqueous citric acid (2x), saturated aqueous sodium bicarbonate (2x), brine (1x), dried over anhydrous magnesium sulfate or sodium sulfate and the solvent removed under reduced pressure to yield the crude product.

## GENERAL PROCEDURE F'

- 15 EDC Coupling of Acid and Amine

- The acid derivative was dissolved in methylene chloride. The amine (1 eq.), N-methylmorpholine (5 eq.), and hydroxybenzotriazole monohydrate (1.2 eq.) were added in sequence. The reaction was cooled to about 0°C and then 1.2 eq. of 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride  
20 was added. The solution was allowed to stir overnight and come to room temperature under N<sub>2</sub> pressure. The reaction mix was worked up by washing the solution with saturated, aqueous Na<sub>2</sub>CO<sub>3</sub>, 0.1M citric acid, and brine before drying with Na<sub>2</sub>SO<sub>4</sub> and removal of solvents to yield crude product. Pure products were obtained by flash chromatography in an appropriate solvent.

- 25 GENERAL PROCEDURE G'

EDC Coupling of Acid and Amine

A round bottom flask was charged with carboxylic acid (1.0 eq.), hydroxybenzotriazole hydrate (1.1 eq.) and amine (1.0 eq.) in THF under nitrogen atmosphere. An appropriate amount (1.1 eq. for free amines and 2.2 eq. for

-- 100 --

hydrochloride amine salts) of base, such as Hunig's base was added to the well stirred mixture followed by EDC (1.1 eq.). After stirring from 4 to 17 hours at room temperature the solvent was removed at reduced pressure, the residue taken up in EtOAc (or similar solvent)/water. The organic layer was washed  
5 with saturated aqueous sodium bicarbonate solution, 1N HCl, brine and dried over anhydrous sodium sulfate. In some cases, the isolated product was analytically pure at this stage while, in other cases, purification via chromatography and/or recrystallization was required prior to biological evaluation.

## GENERAL PROCEDURE H'

Coupling of  $R^1C(X')(X'')C(O)Cl$  with  $H_2NCH(R^2)C(O)XR^3$ 

An excess of oxalyl chloride in dichloromethane was added to the acid derivative together with one drop of DMF. The resulting mixture was stirred for about 2 hours or until bubbling ceases. The solvent was then removed  
15 under reduced pressure and rediluted with dry methylene chloride. To the resulting solution was added about 1.1 eq. of the appropriate amino acid ester and triethylamine (1.1 eq. in methylene chloride). The system was stirred at room temperature for 2 hours and then the solvent was removed under reduced pressure. The residue was dissolved in ethyl acetate, washed with 1N HCl  
20 followed by 1N NaOH. The organic layer was dried over anhydrous sodium sulfate, filtered and the solvent removed under reduced pressure to provide for the desired product.

## GENERAL PROCEDURE I'

P-EPC coupling

25 P-EPC coupling employs an amino acid ester and a substituted acetic acid compound. The acetic acid derivative is well known in the art and is typically commercially available. The amino acid ester is prepared by conventional methods from the known and typically commercially available N-BOC amino acid as described in GENERAL PROCEDURE J' below.

-- 101 --

Specifically, the appropriate amino ester free base (0.0346 mmols) and substituted phenylacetic acid (0.069 mmols) were dissolved in 2.0 mL CHCl<sub>3</sub> (EtOH free), treated with 150 mg of P-EPC (0.87 meq./g) and the reaction was mixed for 4 days at 23°C. The reaction was filtered through a plug of cotton,  
5 rinsed with 2.0 mL of CHCl<sub>3</sub> and the filtrate evaporated under a stream of nitrogen. The purity of each sample was determined by <sup>1</sup>H NMR and ranged from 50% to >95%. Between 8.0 and 15.0 mg of final product was obtained from each reaction and was tested without additional purification.

## GENERAL PROCEDURE J'

10 Synthesis of Amino Acid Esters From the Corresponding N-BOC Amino Acid

## A. Esterification of the Acid.

The N-BOC amino acid was dissolved in dioxane and treated with an excess of alcohol (~1.5 eq.) and catalytic DMAP (100 mg) at 0°C. Stirring was continued until reaction completion whereupon the product was recovered  
15 by conventional methods.

## B. Removal of N-BOC Group.

The N-BOC protected amino acid was dissolved in methylene chloride (0.05M) and treated with 10 eq. of TFA at room temperature under a nitrogen atmosphere. The reaction was monitored by tlc until starting material was  
20 consumed usually within 1-5 hours. An additional 10 eq. of TFA was added to the reaction if the starting material was still present after 5 hours. The reaction was carefully neutralized with Na<sub>2</sub>CO<sub>3</sub>, separated, the organic layer washed with brine and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. The crude amine was then used without purification.

25 Specific exemplification of these procedures are as follows:

1. Racemic (+/-)-N-BOC- $\alpha$ -amino butyric acid (Aldrich) (9.29 g, 0.0457 mol) was dissolved in 100 mL of dioxane and treated with *iso*-butyl

-- 102 --

alcohol (6.26 mL, 0.0686 mol), EDC (8.72 g, 0.0457) and catalytic DMAP (100 mg) at 0°C. After stirring for 17 hours, the organics were evaporated at reduced pressure, the residue diluted with EtOAc washed with NaHCO<sub>3</sub>, brine and dried over Na<sub>2</sub>SO<sub>4</sub>. Evaporation yields 8.42 g (71%) of an oil. C<sub>13</sub>H<sub>23</sub>NO<sub>4</sub> requires: C = 60.21, H = 9.72, and N = 5.40. Anal found: C = 59.91, H = 9.89, and N = 5.67.

The above N-BOC amino acid ester (8.00 g, 0.032 mol) was deprotected as above giving 3.12 g (61%) of the free base as a colorless oil which solidifies upon standing.

2. L-N-BOC-alanine (Aldrich) (8.97 g, 0.047 mol) was dissolved in 100 mL of CH<sub>2</sub>Cl<sub>2</sub>, *iso*-butyl alcohol (21.9 mL, 0.238 mol) and treated with DMAP (100 mg) and EDC (10.0 g, 0.52 mol) at 0°C. The mixture was stirred for 17 hours, diluted with H<sub>2</sub>O, washed with 1.0 N HCl, NaHCO<sub>3</sub>, then brine and the organics were dried over Na<sub>2</sub>SO<sub>4</sub>. Filtration and evaporation yields 11.8 g (quantitative) of L-N-BOC alanine *iso*-butyl ester which is contaminated with a small amount of solvent. A sample was vacuum dried for analytical analysis. C<sub>12</sub>H<sub>23</sub>NO<sub>4</sub> requires: C = 58.79, H = 9.38, and N = 5.71. Anal found: C = 58.73, H = 9.55, and N = 5.96.

The above N-BOC amino acid ester (11.8 g, 0.0481 mol) was deprotected as above. The free base was converted to the corresponding HCl salt using saturated HCl (g)/EtOAc to give L-N-alanine *iso*-butyl ester hydrochloride. Obtained 4.2 g (48%) of a colorless solid. C<sub>7</sub>H<sub>15</sub>NO<sub>2</sub> · HCl requires: C = 46.28, H = 8.88, and N = 7.71. Anal found: C = 46.01, H = 8.85, and N = 7.68.

## GENERAL PROCEDURE K'

Methyl ester formation from amino acids

The amino acid (amino acid or amino acid hydrochloride) is suspended in methanol and chilled to 0°C. HCl gas is bubbled through this solution for 5 minutes. The reaction is allowed to warm to room temperature then stirred for 4 hours. The solvents are then removed at reduced pressure to afford the desired amino acid methyl ester hydrochloride. This product is usually used without further purification.

## Example A'

10                    **Synthesis of free and polymer bound PEPC**N-ethyl-N'-3-(1-pyrrolidinyl)propylurea

To a solution of 27.7 g (0.39 mol) ethyl isocyanate in 250 mL chloroform was added 50 g (0.39 mol) 3-(1-pyrrolidinyl)propylamine dropwise with cooling. Once the addition was complete, the cooling bath was removed and the reaction mixture stirred at room temperature for 4 hours. The reaction mixture was then concentrated under reduced pressure to give 74.5 g (96.4%) of the desired urea as a clear oil.

1-(3-(1-pyrrolidinyl)propyl)-3-ethylcarbodiimide (P-EPC)

To a solution of 31.0 g (0.156 mol) N-ethyl-N'-3-(1-pyrrolidinyl)propylurea in 500 mL dichloromethane was added 62.6 g (0.62 mol) triethylamine and the solution was cooled to 0°C. To this solution were then added 59.17 g (0.31 mol) 4-toluenesulfonyl chloride in 400 mL dichloromethane dropwise at such a rate as to maintain the reaction at 0-5°C. After the addition was complete, the reaction mixture was warmed to room temperature and then heated to reflux for 4 hours. After cooling to room temperature, the reaction mixture was washed with saturated aqueous potassium carbonate (3 x 150 mL). The aqueous phases were combined and extracted with dichloromethane. All organic phases were combined and concentrated under reduced pressure. The resultant orange slurry was suspended in 250 mL diethyl ether and the solution

-- 104 --

decanted off from the solid. The slurry/decantation process was repeated 3 more times. The ether solutions were combined and concentrated under reduced pressure to give 18.9 g (67%) of the desired product as a crude orange oil. A portion of the oil was distilled under vacuum to give a colorless oil  
5 distilling at 78-82°C (0.4 mm Hg).

Preparation of a polymer supported form of 1-(3-(1-pyrrolidinyl)propyl)-3-ethylcarbodiimide (P-EPC)

A suspension of 8.75 g (48.3 mmol) 1-(3-(1-pyrrolidin-yl)propyl)-3-ethylcarbodiimide and 24.17 g (24.17 mmol) Merrifield's resin (2% cross-linked, 200-400 mesh, chloromethylated styrene/divinylbenzene copolymer, 1  
10 meq. Cl/g) in dimethylformamide was heated at 100°C for 2 days. The reaction was cooled and filtered and the resulting resin washed sequentially with 1L DMF, 1L THF and 1L diethyl ether. The remaining resin was then dried under vacuum for 18 hours.

A mixture of 35.64 g (0.4 mol) of (D,L)-alanine (Aldrich) (or L-alanine (Aldrich)); 44 mL (0.6 mol) of thionyl chloride (Aldrich) and 200 mL of isobutanol was refluxed for 1.5 hours and the volatiles were removed  
20 completely on a rotavapor of 90°C under reduced pressure to give (D,L)-alanine *iso*-butyl ester hydrochloride (or L-alanine *iso*-butyl ester hydrochloride), which was pure enough to be used for further transformations.

Example C'

**Preparation of 3,5-dichlorophenylacetic acid**

25 To a solution of 3.5 g of 3,5-dichlorobenzyl alcohol (Aldrich) in 75 mL of dichloromethane at 0°C was added 1.8 mL of methane sulfonylchloride followed by 3.5 mL of triethylamine added dropwise. After 2 hours the solution was diluted to 150 mL with dichloromethane, washed with 3N HCl,

-- 105 --

saturated aqueous  $\text{NaHCO}_3$  dried with  $\text{Na}_2\text{SO}_4$  and the solvents removed to yield the desired 3,5-dichlorobenzyl methanesulfonate as a yellow oil that was used without purification.

5 The crude sulfonate was dissolved in 50 mL of DMF at  $0^\circ\text{C}$  and then 3 g of KCN was added. After 2 hours an additional 50 mL of DMF was added and the solution was stirred for 16 hours. The red solution was diluted with 1 L of  $\text{H}_2\text{O}$  and acidified to pH 3 with 3N HCl. The aqueous solution was extracted with dichloromethane. The combined organics were washed with 3N HCl, dried with  $\text{Na}_2\text{SO}_4$  and the solvents removed at reduced pressure to yield crude  
10 3,5-dichlorophenylacetonitrile which was used without purification.

The nitrile was added to a mixture of 40 mL of concentrated sulfuric acid and 50 mL  $\text{H}_2\text{O}$  and heated to reflux for 48 hours, cooled to room temperature and stirred for 48 hours. The reaction was diluted into 1 L of crushed ice, warmed to room temperature and extracted with 2 x 200 mL of  
15 dichloromethane and 2 x 200 mL of ethylacetate. Both sets of organics were combined and washed with saturated aqueous  $\text{NaHCO}_3$ . The  $\text{NaHCO}_3$  fractions were combined and acidified to pH 1 with 3N HCl. The white solid was too fine to filter and was extracted out with 2 X 200 mL of dichloromethane. The combined organics were dried with  $\text{Na}_2\text{SO}_4$  and the solvents removed at reduced  
20 pressure to yield crude 3,5-dichlorophenylacetic acid as a white solid. The solid was slurried with hexane and filtered to get 1.75g of white solid.

**Synthesis of *N*-(3,5-difluorophenylacetyl)-*L*-phenylglycine *iso*-butyl ester**

The 3,5-difluorophenylacetic acid (Aldrich) was EDC coupled to *L*-phenylglycine methyl ester hydrochloride (Bachem) via General Procedure F above.

DMF (0.5 mL, catalytic) was added followed by the dropwise addition of oxalyl chloride (18 mL, 0.20 mol) over a 5 minute period. The reaction was stirred for 3 h and then rotoevaporated at reduced pressure to a residue which was placed on a high vacuum pump for 1 h to afford 3,5-difluorophenylacetyl chloride as a thin yellow oil. Other acid chlorides can be prepared in a similar manner.

##### Synthesis of 3,5-Difluorophenyl- $\alpha$ -fluoroacetic Acid

Methyl 3,5-difluoromandelate was prepared following General Procedure G below and using commercially available 3,5-difluoromandelic acid. The resultant  $\alpha$ -hydroxy methyl ester was fluorinated according to the general procedure described in W. J. Middleton, et al., *Org. Synth. Col. Vol. VI*, 835. Specifically, a solution of diethylaminosulfur trifluoride (1.1 eq) in  $\text{CH}_2\text{Cl}_2$  was cooled to 0°C and treated with methyl 3,5-difluoromandelate (1.0 eq) as a solution in  $\text{CH}_2\text{Cl}_2$ . After 10 min. the cooling bath was removed and the

-- 149 --

reaction was stirred at ambient temperature for 30 min. The reaction was monitored by tlc ( $R_f = 0.65$ , 1:1 ethyl acetate/hexanes). The mixture was then poured onto ice and the layers separated. The organic phase was washed with saturated aqueous  $\text{NaHCO}_3$  and brine. The organic layer was dried over  $\text{Na}_2\text{SO}_4$ , filtered, and concentrated *in vacuo*. The product was purified by LC2000 chromatography (180 mL/min) using 10% EtoAc/hexanes as the eluent. The resulting methyl 3,5-difluorophenyl- $\alpha$ -fluoroacetate was hydrolyzed by dissolving the ester in 70% aqueous dioxane and treating with lithium hydroxide (2.0 eq.). No starting material remained by tlc after 2 h. The dioxane was removed via rotary evaporation. The aqueous mixture was first washed with ethyl acetate and then acidified with 0.01 N HCl. The aqueous layer was extracted with ethyl acetate. The organic phase was washed with brine, dried over  $\text{Na}_2\text{SO}_4$ , filtered, and concentrated. The crude solid was recrystallized from ethyl acetate/hexanes affording 3,5-difluorophenyl- $\alpha$ -fluoroacetic acid as a white solid having a melting point of 90-110°C.

## Example D3

Synthesis of  
Methyl (S)-2-Amino-2-(6-methoxy-2-naphthyl)acetate

-- 150 --

(S)-2-(*tert*-Butoxycarbonylamino)-2-(6-methoxy-2-naphthyl)acetic acid was prepared from 2-(6-methoxy-2-naphthyl)acetic acid according to the general method described by D.A. Evans, et al., *J. Amer. Chem. Soc.*, (1990), 112, 4011-4030. Briefly, (S)-3-(6-methoxy-2-naphthylacetyl)-4-benzyl-2-  
5 ozazolidinone was converted to (S)-3-[(S)-6-methoxy-2-naphthyl- $\alpha$ -azidoacetyl]-4-benzyl-2-ozazolidinone via standard enolate azidation procedures using potassium 1,1,1,3,3,3-hexamethyldisilazane and trimethylsilyl azide at -78°C. Treatment of the azide derivative with 3 equivalents of lithium hydroxide in THF then provided (S)-2-azido-2-(6-methoxy-2-naphthyl)acetic acid. Reduction  
10 of this intermediate, as its sodium salt, in 1:1 1,4-dioxane/water (0.05 M) with 1 atm of hydrogen, 10% Pd/C at 25°C afforded (S)-2-azido-2-(6-methoxy-2-naphthyl)acetic acid, which was then converted, without isolation, to its N-Boc derivative on treatment with 1.4 equivalents of di-*tert*-butyl dicarbonate and 0.47 equivalents of sodium carbonate. The product was isolated by the  
15 acidification to pH 2 with 1 N NaHSO<sub>4</sub> and extraction with three portions of ethyl acetate. The product was recrystallized from ethyl acetate/hexanes to afford a white solid, m.p. = 176°C (shrink); 197-199°C (dec).

NMR data was as follows:

<sup>1</sup>HMR (DMSO-*d*<sub>6</sub>):  $\delta$  = 12.78 (s, 1H), 7.84-7.77 (m, 3H), 7.62 (d, J=8  
20 Hz, 1H), 7.49 (d, J=8 Hz, 1H), 7.31 (d, J=2 Hz, 1H), 7.17 (dd, J=9, 2 Hz, 1H), 5.22 (d, J=8 Hz, 1H), 3.87 (s, 3H), 1.39 (s, 9H).

(S)-2-(*tert*-Butoxycarbonylamino)-2-(6-methoxy-2-naphthyl)acetic acid was then converted into the methyl ester using General Procedure G below. The methyl ester was then dissolved in CH<sub>2</sub>Cl<sub>2</sub> and this solution cooled to 0°C.  
25 Trifluoroacetic acid (50 molar eq.) was added and the reaction was allowed to warm to room temperature and stirring was continued for 2 hrs. The reaction mixture was then concentrated and the residue extracted into CH<sub>2</sub>Cl<sub>2</sub> and washed with sodium bicarbonate solution. The organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to yield methyl (S)-2-amino-2-(6-methoxy-2-  
30 naphthyl)acetate.

## Example D4

## Synthesis of

Methyl 2-Amino-2-(thieno[2,3-*b*]thiophen-2-yl)acetate

To a 3.75 mole equivalents of sodium hydride (oil free) was added DMF  
5 and the resulting mixture was cooled to 0°C. A solution of methyl thieno[2,3-*b*]thiophen-2-carboxylate (1 mole eq.) and methyl methylsulfinyl methyl sulfide (1.1 mole eq.) in DMF was then added dropwise and the reaction mixture was stirred at 0°C for 30 min and then allowed to warm to room temperature and stirring was continued for 3 h. The reaction was then quenched with methanol  
10 and the product extracted into EtOAc. The organic extracts were washed with water followed by brine, and then dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to give a gummy brown oil. The residue was slurried in diethyl ether and the resulting solid collected. The solid was then dissolved in hot ethyl acetate and decolorizing carbon was added. The mixture was then filtered and solvent  
15 removed to give a solid, which was used without further purification.

Acetic anhydride (10 mole eq.) and acetic acid (1.8 mole eq.) were mixed together and heated to 70°C for 15 min. and then cooled to 65°C. The solid sulfone from above was added in portions and the reaction was allowed to stir at 70°C for 30 min. and then cooled and concentrated. The resulting solid was  
20 taken up in ethyl acetate and washed with sodium bicarbonate solution, followed by 1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solution. The solution was then dried over MgSO<sub>4</sub>, filtered and concentrated to give methyl 2-keto-2-(thieno[2,3-*b*]thiophen-2-yl)thioacetate as a solid, which was used without further purification.

To the 2-keto compound (0.0165 moles) (4.0g) was added 270 mL of  
25 methanol and 16.5 mL of 1 N NaOH. The reaction was allowed to stir for 6 h at room temperature and then methoxyamine (1.38 g, 0.0165 moles) was added and stirring was continued for 18 h. The reaction mixture was then concentrated and the residue dissolved in ethyl acetate and washed with water. The aqueous layer was then acidified with in HCl and the oily product was

-- 152 --

extracted into ethyl acetate and washed with brine. The organic layer was dried over  $\text{MgSO}_4$ , filtered and concentrated to give 4.0 g of 2-(hydroxyimino)-2-(thieno[2,3-*b*]thiophen-2-yl)acetic acid as a yellow solid.

5 The methyl ester was then prepared using General Procedure G below and the oxime was reduced to an amino group using General Procedure R below to afford methyl 2-amino-2-(thieno[2,3-*b*]thiophen-2-yl)acetate.

*D,L*- $\alpha$ -Methylphenylglycine Ethyl Ester

-- 154 --

The title was prepared using the procedures described in J.J. Fitt and H. W. Gschwend, *J. Org. Chem.*, 42, No. 15, 2639 (1977). More specifically, D,L-phenylglycine (Aldrich) was stirred in dimethylformamide dimethylacetal and the mixture was heated at reflux under an atmosphere of dry nitrogen for 4  
5 hours. After cooling, the mixture was concentrated under reduced pressure to provide a yellow oily solid. The mixture was slurried in diethyl ether and filtered through Celite. The filtrate was concentrated to an orange oil which was purified by vacuum distillation to provide a yellow oil which solidified. The yellow solid was stirred in dry THF at -20 C under dry nitrogen. Lithium  
10 bis(trimethylsilyl)amide (1.05 eq, 1.0M solution in THF) was added dropwise. The resulting mixture was allowed to warm to -10 C and stirring was continued for 1 hour at that temperature. Methyl iodide (1.05 eq) was added and the mixture was allowed to warm ambient temperature with stirring. After 14 hours, the mixture was concentrated. The residue was partitioned between  
15 aqueous potassium carbonate and chloroform. The organic portion was dried (sodium sulfate) and concentrated under reduced pressure. The product was purified by silica gel chromatography to yield a yellow oil. The yellow oil was stirred in absolute ethanol. Dry zinc chloride (4 eq.) was added and the mixture was heated at reflux. After 14 hours, the mixture was concentrated  
20 under reduced pressure to provide a yellow oil. The oil was partitioned between aqueous potassium carbonate and chloroform. The organic portion was dried (sodium sulfate) and concentrated under reduced pressure. The title compound was purified by silica gel chromatography.

#### tert-Butyl Ester Preparation I

To a solution of an *N*-CBZ-protected amino acid in CH<sub>2</sub>Cl<sub>2</sub> was added 1.5 equivalents of *N,N'*-diisopropyl-*O*-*t*-butylisourea (prepared by standard literature methods such as those found in *Synthesis* (1979), p. 561), and the reaction was heated to reflux for 17 h. An additional 1.5 equivalents of isourea

25

-- 168 --

were then added, and reflux was continued for another 7 h. The reaction was then cooled to room temperature and filtered through a bed of Celite 545, then stripped to dryness to leave a clear oil. The residue was dissolved in hexanes and filtered to remove solids, and the filtrate was washed with saturated aqueous NaHCO<sub>3</sub>, water, saturated aqueous NaCl, and dried over MgSO<sub>4</sub>. The solution was concentrated under reduced pressure to leave the product.

## GENERAL PROCEDURE J

tert-Butyl Ester Preparation II

The reaction was conducted in a sealed tube using the appropriate carboxylic acid, a catalytic amount of H<sub>2</sub>SO<sub>4</sub> (0.03 eq.) and an excess of condensed *iso*-butylene in dioxane or CH<sub>2</sub>Cl<sub>2</sub> at -20°C. The reaction times varied from about 48 hours to about 120 hours. When the reaction was complete, the solvent was removed under reduced pressure and the residue dissolved in diethyl ether. This solution was washed with sodium bicarbonate solution and the organic layer dried over sodium sulfate, filtered and solvent removed. The resulting product was purified using standard procedures, such as HPLC or titration using, for example, diethyl ether/hexanes.

## GENERAL PROCEDURE K

Amide Preparation I

To a solution of 3 equivalents of the desired amine in 1,2-dichloroethane was added 5.2 equivalents triethylaluminum subsurface. After stirring for 30 minutes at room temperature, a solution of the desired ester dissolved in 1,2-dichloroethane was added. The reaction was refluxed until tlc showed complete conversion, typically 3h. The reaction was then cooled to 0°C and quenched with 10% aqueous hydrochloric acid (Note: the acid should be added slowly as some foaming occurs during its addition). The mixture was transferred to a separatory funnel and the layers were separated. The aqueous phase was washed with ethyl acetate, and the organic phases were washed with saturated

-- 169 --

aqueous NaCl, dried over MgSO<sub>4</sub>, and concentrated under reduced pressure to leave the crude product.

Alternatively, if the product is acid soluble, after the reaction is quenched, the reaction volume was reduced to about one-third of its initial volume under reduced pressure. To the resulting solution was added 20% aqueous potassium sodium tartrate (Rochelle's salt) and ethyl acetate. The pH of the solution was then adjusted to -13, and the aluminum salts dissolved in the aqueous solution. The organic phase was separated, and the aqueous phase was extracted with ethyl acetate. The combined organic solution was washed with saturated aqueous NaCl, dried over MgSO<sub>4</sub>, and concentrated under reduced pressure to leave the crude product.

#### Synthesis of *tert*-butyl *N*-[*N*-(3,5-Difluorophenylacetyl)- L-alaninyl]-(*S*)-2-aminohexanoate

##### Step A - *t*-Butyl Ester Formation

10 To a solution of Z-norleucine-OH in CH<sub>2</sub>Cl<sub>2</sub> was added 1.5 equivalents of  
*N,N'*-diisopropyl-*O-t*-butylisourea (prepared by the method of *Synthesis* (1979)  
p.561 for review) and the reaction was heated to reflux for 17 hours. An  
additional 1.5 equivalents of isourea was then added, and reflux was continued  
for another 7 hours. The reaction was then cooled to room temperature and  
15 filtered through a bed of Celite 545, then stripped to dryness to leave a clear  
oil. The residue was dissolved in hexanes and filtered to remove solids, and  
the filtrate was washed with saturated aqueous NaHCO<sub>3</sub>, water, saturated  
aqueous NaCl, and dried over MgSO<sub>4</sub>. The solution was concentrated under  
reduced pressure to leave the product.

##### Step B - CBZ Removal

20 The CBZ-protected amino ester was dissolved in ethanol in a hydrogenation  
flask and a catalytic amount of 10% Pd/C was added. The mixture was  
hydrogenated at 20 psi H<sub>2</sub> on a Parr shaker for 30 min. The reaction was then  
filtered through a pad of Celite 545 and stripped free of solvent on a rotary  
evaporator to yield the product, norleucine *tert*-butyl ester hydrochloride.

##### 25 Step C

Following General Procedure D and using *N*-(3,5-difluorophenylacetyl)-L-  
alanine (from Example B2 above) and the norleucine *tert*-butyl ester  
hydrochloride, the title compound was prepared as a semi-solid. The reaction  
was monitored by tlc (R<sub>f</sub> = 0.41 in 50% EtOAc/hexanes) and the product was

purified by flash chromatography using 50% EtOAc/hexanes as the eluent, followed by preparative plate chromatography using 50% EtOAc/hexanes as the eluent.

#### Synthesis of Methyl *N*-[*N*-(3,5-Difluorophenylacetyl)- L-alaninyl]-(*S*)-2-amino-3-(4-pyridyl)propionate

##### Step A - Preparation of 3-(3-pyridyl)alanine methyl ester dihydrochloride

10 Sodium metal (1.40 g, 61 mmol) was dissolved in EtOH (100mL) and diethyl acetamidomalonate (6.62 g, 30.5 mmol) and 3-picolylchloride hydrochloride (5.00g, 30.5 mmol) were added. The mixture was heated to reflux for 6 hours, and then cooled and filtered to remove NaCl (washed with EtOH). The solvent was removed *in vacuo* and the mixture was taken up into saturated aqueous  $\text{NaHCO}_3$  (100 mL) and extracted with EtOAc (3 x 100 m

L).

15 The solvent was removed and the residue purified by silica gel flash chromatography (95:5  $\text{CH}_2\text{Cl}_2/\text{MeOH}$ ) to give diethyl 2-(3-pyridylmethyl)-2-acetamidomalonate (2.84 g, 30%).

Diethyl 2-(3-pyridylmethyl)-2-acetamidomalonate was dissolved in 6N HCl (30 mL) and heated to reflux for 19 hours whereupon it was cooled to room

The intermediate amino acid dihydrochloride salt was taken up into MeOH (30 mL) saturated with HCl gas and stirred for 3.5 hours. The MeOH/HCl was removed by evaporation *in vacuo* to give 3-(3-pyridyl)alanine methyl ester dihydrochloride (2.235 g, 100%).

##### Synthesis of

Methyl *N*-[*N*-(3,5-Difluorophenylacetyl)-*L*-alaninyl]-2-amino-3-morpholinopropionate

##### Step A methyl (2-N-CBZ-amino)-3-morpholino-propionate

To a solution of *N*-CBZ-dehydro-alanine methyl ester (Sigma) in acetonitrile was added 2.0 equivalent of morpholine and 0.25 equivalents of anhydrous ferric chloride. The mixture was stirred for 16 hours and monitored by TLC. The solvent was stripped off and the residue extracted with ethyl acetate and washed with 1N HCl. The aqueous layer was basified with 1N potassium carbonate to pH = 9 and extracted with ethyl acetate again, dried over sodium sulfate and rotovapped to dryness to give methyl (2-N-CBZ-amino)-3-morpholino-propionate as a clear tan oil. ##### Step A -- Synthesis of (*S*)-3-(Hex-4-enoyl)-4-(phenylmethyl)-2-oxazolidinone

To a mechanically stirred solution of 9.50 g (83.2 mmol, 1.10 equiv.) of 4-hexenoic acid (commercially available from Lancaster, Catalog #252-427-6) and 13.9 mL (10.1 g, 99.7 mmol, 1.33 equiv.) of triethylamine in 150 mL of dry THF, cooled to  $-78^\circ\text{C}$  under dry  $\text{N}_2$ , was added 10.71 mL (10.49 g, 87.0 mmol, 1.15 equiv.) of pivaloyl chloride (Aldrich). The mixture was warmed to  $0^\circ\text{C}$  for 60 min, and then recooled to  $-78^\circ\text{C}$ . A solution of 13.4 g (75.6 mmol, 1.00 equiv) of (*S*)-(-)-(phenylmethyl)-2-oxazolidone (Aldrich) and 22 mg of triphenylmethane (indicator) in 150 mL of dry THF, stirred at  $-30^\circ\text{C}$  to  $-45^\circ\text{C}$  under  $\text{N}_2$ , was treated dropwise with *n*-butyllithium ( $\sim 2.5$  M in hexanes) (Aldrich) until an orange color persisted ( $\sim 30$  mL required). The resulting solution was cooled to  $-78^\circ\text{C}$  and then added, via rapid cannulation, to the above stirred mixture containing the mixed anhydride. The residual lithiated oxazolidone was rinsed in with two 10-mL portions of dry THF and the

resulting mixture was stirred at -78°C for 1.5 h, and then at 0°C for 1 h. The mixture was partitioned between CH<sub>2</sub>Cl<sub>2</sub> and pH 7 phosphate buffer. The CH<sub>2</sub>Cl<sub>2</sub> phase was washed with saturated aqueous NaHCO<sub>3</sub> followed by half-saturated aqueous NaCl, dried (MgSO<sub>4</sub>), and evaporated *in vacuo*. The residual

5 cream-colored solid (22.4 g) was chromatographed (Waters Prep 2000, 5.0 cm x 25 cm 10 μ Kromasil KR60-10SIL-5025 column) in two batches eluting with 85:15 hexanes/EtOAc. The chromatographed product was recrystallized from hexane to yield 14.34 g (first crop, 69%) of the title compound as fine white needles. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 7.37-7.20 (m, 5H, -C<sub>6</sub>H<sub>5</sub>), 5.60-

15           Step B --       Synthesis of (4S)-3-[(S)-2-Azidohept-4-enoyl]-4-(phenylmethyl)-2-oxazolidinone

A solution of 5.47g (20.0 mmol, 1.00 equiv) of the product from Step A above in 60 mL of dry THF, stirred at -78°C under dry N<sub>2</sub>, was added via rapid cannulation to a stirred, cooled (-78°C) solution of 43.6 mL (22.0 mmol,

20 1.10 equiv) of potassium hexamethyldisilazide (0.505 M in toluene) (Aldrich) and 60 mL of dry THF. The residual imide solution was rinsed in with two 5-mL portions of dry THF. The resulting solution was stirred at -78°C for 30 min. To the above solution of the K-enolate, stirred at -78°C under dry N<sub>2</sub>, was added a cooled (-78°C) solution of 7.43 g (24.0 mmol, 1.2 equiv) of trisyl

The residual mixed anhydride was rinsed in with 7 mL of THF and 1.1 g (13.1 mmol, 4.0 equiv.) of NaHCO<sub>3</sub> powder and 5 mL of H<sub>2</sub>O was added. The mixture was stirred at 0°C for 5 h. An additional 1.1 g (13.1 mmol, 4.0 equiv.) of NaHCO<sub>3</sub> powder and 5 mL of H<sub>2</sub>O was added and the mixture was stirred at 20°C for 1.5 h. The mixture was filtered to remove the gelatinous precipitate, and the filter cake was washed with several portions of EtOAc. The filtrate was washed with saturated aqueous NaHCO<sub>3</sub> (the aqueous phase was back-extracted with 3 portion of EtOAc), followed by pH 4-5 phosphate buffer (the aqueous phase was back-extracted with 3 portions of EtOAc). The solution was stirred at 0°C for 40 min. Toluene (15 mL) was added and the mixture was evaporated *in vacuo* on the rotary evaporator. The addition of toluene and solvent evaporation was repeated. The residue was dissolved in 20 mL of CH<sub>2</sub>Cl<sub>2</sub> and the solution was cooled to 0°C under dry N<sub>2</sub>. To this was added 1.35 mL (1.00 g, 7.74 mmol, 3.0 equiv) of ethyldiisopropylamine (Aldrich), followed by the dropwise addition at ≤ 6°C of 0.728 mL (0.938 g, 5.16 mmol, 2.0 equiv) of 3,5-difluorophenylacetyl chloride (prepared from 3,5-difluorophenylacetic acid (Aldrich) using General Procedure H'). The resulting solution was stirred at 0°C for 2 h. Excess saturated aqueous NaHCO<sub>3</sub> was added and the two phase mixture was stirred in an ice bath for 30 min. The mixture was diluted with CH<sub>2</sub>Cl<sub>2</sub> and washed successively with aqueous NaHCO<sub>3</sub>/Na<sub>2</sub>CO<sub>3</sub> (pH 10), 1 N aqueous NaHSO<sub>4</sub>, and saturated aqueous NaCl. The CH<sub>2</sub>Cl<sub>2</sub> solution was dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated *in vacuo* to afford 1.17 g of a yellow solid. This was recrystallized from EtOAc to yield 602 mg (63%) of the title compound as a fluffy white solid. This material was found by 300 MHz <sup>1</sup>H NMR analysis to consist of a 92:8 mixture of E and Z isomers, respectively.

- 15           C<sub>25</sub>H<sub>21</sub>N<sub>2</sub>O<sub>4</sub>F<sub>2</sub> (MW = 470.44); mass spectroscopy (MH<sup>+</sup>) 470.1.

Preparation of (4-fluorophenyl)glycine:

- (S)-(-)-4-Benzyl-2-oxazolidinone (15.0 g, 93 mmol) (Aldrich) was dissolved in THF (100 mL). The solution was cooled to -70°C and reaction flask was purged twice with nitrogen. n-Butyl lithium (44.6 mL, 2.0M, 89
- 20   mmol) was added to form a solid precipitate which broke up on stirring to afford a slurry. 4-Fluorophenylacetyl chloride 16.1 g, 93 mmol) (Aldrich) was added to afford a light green solution and stirring was continued for 45 minutes. The reaction mixture was then stirred at room temperature for 1 hour. The reaction mixture was then treated with saturated sodium bisulfate
- 25   (100 mL) and ethyl acetate (100 mL). The organic phase was washed with water, followed by brine. The organic phase was then dried over anhydrous sodium sulfate and concentrated under reduced pressure to afford an oil. The oil was crystallized to afford 24.4 g of 1-(4-fluorophenylacetyl)-(S)-(-)-4-Benzyl-2-oxazolidinone.

-- 331 --

Potassium hexamethyldisilazane (140 mL, 0.5M, 70.0 mmol) was added to THF (80 mL). The solution was cooled to -50°C under nitrogen and a cold solution (-60°C) of 1-(4-fluorophenylacetyl)-(S)-(-)-4-benzyl-2-oxazolidinone (15.0 g, 46 mmol) in THF (100 mL). The resulting mixture was allowed to stir at -70°C for 1 hour and to warm to about -20°C. The mixture was re-cooled to -70°C and a cold solution (-65°C) of trisyl azide (21.6 g, 70.0 mmol) was added. The mixture was allowed to stir for about 15 min. while warming to -45°C and then glacial acetic acid (18 mL) was added. The mixture was then stirred at about 30°C for 3 hours. A precipitate formed and was removed by filtration. The filtrate was concentrated by 50 and then washed with water, saturated sodium bicarbonate solution and brine. The organic phase was dried over sodium sulfate, concentrated under reduced pressure to afford 37.7 g of crude 1-[2-(4-fluorophenyl)-2-azidoacetyl]-(S)-(-)-4-benzyl-2-oxazolidinone.

Crude 1-[2-(4-fluorophenyl)-2-azidoacetyl]-(S)-(-)-4-benzyl-2-oxazolidinone (10.0 g, 28.0 mmol) was dissolved in 100 mL of THF and 100 mL of methanol and trifluoroacetic acid (4.31 mL, 75.3 mmol) was added. Palladium on carbon (10%, 2.0 g) was added and the mixture was hydrogenated on a Paar shaker at 50 psi overnight at room temperature. The reaction mixture was then filtered through a plug of Celite and the solid cake was rinsed with 100 mL of methanol. The filtrate was concentrated to afford 1-[2-(4-fluorophenyl)-2-aminoacetyl]-(S)-(-)-4-benzyl-2-oxazolidinone trifluoroacetate salt as a yellowish oil.

To a mixture of THF and de-ionized water (50 mL/50 mL) was added 1-[2-(4-fluorophenyl)-2-aminoacetyl]-(S)-(-)-4-benzyl-2-oxazolidinone trifluoroacetate salt (4.14 g, 9.7 mmol) and lithium hydroxide monohydrate (1.22 g, 29 mmol). The homogenous solution was stirred for 2 hours at room temperature at which time Tlc indicated complete disappearance of starting material. The mixture was extracted with dichloromethane (3 x 100 mL) and

-- 332 --

the aqueous phase was acidified to pH 2-3 while cooling in an ice-bath. A precipitate formed. The mixture was then cooled in an ice-bath for 1.5 hours and then filtered. The solid was washed with water followed by pentane to afford 4-fluorophenylglycine hydrochloride.

5 thiocarboxamide in 4 mL 30% HBr in acetic acid was stirred for 1 hour. The  
volatile materials were removed under reduced pressure and the crude  
phenylglycine thiocarboxamide hydrobromide was obtained as a pale solid. The  
material was utilized without further purification.

To a stirred solution of 486 mg of (3,5-difluorophenylacetyl)-L-alanine  
10 (from B2) in 30 mL of dichloromethane was added 383 mg of EDCI, 270 mg of

dichloromethane. The reaction mixture was stirred at ambient temperature for  
72 hours. The reaction mixture was partitioned between water and  
15 dichloromethane and the organic phase was washed with 1N HCl solution,  
followed by saturated aqueous sodium bicarbonate solution. Removal of  
solvent afforded the crude product, which was purified by chromatography on

##### Cellular Screen for the Detection of Inhibitors of $\beta$ -Amyloid Production

Numerous compounds of formula I above were assayed for their ability to inhibit  $\beta$ -amyloid production in a cell line possessing the Swedish mutation. This screening assay employed cells (K293 = human kidney cell line) which  
15 were stably transfected with the gene for amyloid precursor protein 751 (APP751) containing the double mutation Lys<sub>651</sub>Met<sub>652</sub> to Asn<sub>651</sub>Leu<sub>652</sub> (APP751 numbering) in the manner described in International Patent Application Publication No. 94/10569<sup>8</sup> and Citron et al.<sup>12</sup>. This mutation is commonly called the Swedish mutation and the cells, designated as "293 751 SWE", were  
20 plated in Corning 96-well plates at 1.5-2.5 x 10<sup>4</sup> cells per well in Dulbecco's minimal essential media plus 10% fetal bovine serum. Cell number is important in order to achieve  $\beta$ -amyloid ELISA results within the linear range of the assay (~0.2 to 2.5 ng per mL).

25 Following overnight incubation at 37°C in an incubator equilibrated with 10% carbon dioxide, media were removed and replaced with 200  $\mu$ L of a compound of formula I (drug) containing media per well for a two hour pretreatment period and cells were incubated as above. Drug stocks were prepared in 100% dimethylsulfoxide such that at the final drug concentration

-- 374 --

used in the treatment, the concentration of dimethylsulfoxide did not exceed 0.5% and, in fact, usually equaled 0.1%.

At the end of the pretreatment period, the media were again removed and replaced with fresh drug containing media as above and cells were  
5 incubated for an additional two hours. After treatment, plates were centrifuged in a Beckman GPR at 1200 rpm for five minutes at room temperature to pellet cellular debris from the conditioned media. From each well, 100  $\mu$ L of conditioned media or appropriate dilutions thereof were transferred into an ELISA plate precoated with antibody 266<sup>14</sup> against amino acids 13-28 of  $\beta$ -  
10 amyloid peptide as described in International Patent Application Publication No. 94/10569<sup>8</sup> and stored at 4°C overnight. An ELISA assay employing labelled antibody 6C6<sup>14</sup> against amino acids 1-16 of  $\beta$ -amyloid peptide was run the next day to measure the amount of  $\beta$ -amyloid peptide produced.

Cytotoxic effects of the compounds were measured by a modification of  
15 the method of Hansen, et al.<sup>13</sup>. To the cells remaining in the tissue culture plate was added 25  $\mu$ L of a 3,(4,5-dimethylthiazol-2-yl)2,5-diphenyltetrazolium bromide (MTT) stock solution (5 mg/mL) to a final concentration of 1 mg/mL. Cells were incubated at 37°C for one hour, and cellular activity was stopped by the addition of an equal volume of MTT lysis buffer (20% w/v sodium  
20 dodecylsulfate in 50% dimethylformamide, pH 4.7). Complete extraction was achieved by overnight shaking at room temperature. The difference in the OD<sub>562nm</sub> and the OD<sub>650nm</sub> was measured in a Molecular Device's UV<sub>max</sub> microplate reader as an indicator of the cellular viability.

The results of the  $\beta$ -amyloid peptide ELISA were fit to a standard curve  
25 and expressed as ng/mL  $\beta$ -amyloid peptide. In order to normalize for cytotoxicity, these results were divided by the MTT results and expressed as a percentage of the results from a drug free control. All results are the mean and standard deviation of at least six replicate assays.

-- 375 --

The test compounds were assayed for  $\beta$ -amyloid peptide production inhibition activity in cells using this assay. The results of this assay demonstrate that, each of the compounds within this invention tested reduced  $\beta$ -amyloid peptide production by at least 30% as compared to control.

#### Example 410

##### **In Vivo Suppression of $\beta$ -Amyloid Release and/or Synthesis**

This example illustrates how the compounds of this invention could be tested for *in vivo* suppression of  $\beta$ -amyloid release and/or synthesis. For these experiments, 3 to 4 month old PDAPP mice are used [Games et al., (1995)  
10 *Nature* 373:523-527]. Depending upon which compound is being tested, the compound is usually formulated at either 5 or 10 mg/ml. Because of the low solubility factors of the compounds, they may be formulated with various vehicles, such as corn oil (Safeway, South San Francisco, CA); 10% EtOH in corn oil (Safeway); 2-hydroxypropyl- $\beta$ -cyclodextrin (Research Biochemicals  
15 International, Natick MA); and carboxy-methyl-cellulose (Sigma Chemical Co., St. Louis MO). Specifically, for example 141 the vehicle was carboxy-methyl-cellulose (Sigma).

The mice are dosed subcutaneously with a 26 gauge needle and 3 hours later the animals are euthanized via CO<sub>2</sub> narcosis and blood is taken by cardiac  
20 puncture using a 1 cc 25G 5/8" tuberculin syringe/needle coated with solution of 0.5 M EDTA, pH 8.0. The blood is placed in a Becton-Dickinson vacutainer tube containing EDTA and spun down for 15 minutes at 1500 xg at 5°C. The brains of the mice are then removed and the cortex and hippocampus are dissected out and placed on ice.

25

##### 1. Brain Assay

To prepare hippocampal and cortical tissue for enzyme-linked immunosorbent assays (ELISAs) each brain region is homogenized in 10

-- 376 --

volumes of ice cold guanidine buffer (5.0 M guanidine-HCl, 50 mM Tris-HCl, pH 8.0) using a Kontes motorized pestle (Fisher, Pittsburgh PA). The homogenates are gently rocked on a rotating platform for three to four hours at room temperature and stored at -20°C prior to quantitation of  $\beta$ -amyloid.

5           The brain homogenates are diluted 1:10 with ice-cold casein buffer [0.25% casein, phosphate buffered saline (PBS), 0.05% sodium azide, 20  $\mu$ g/ml aprotinin, 5 mM EDTA, pH 8.0, 10  $\mu$ g/ml leupeptin], thereby reducing the final concentration of guanidine to 0.5 M, before centrifugation at 16,000 xg for 20 minutes at 4°C. The  $\beta$ -amyloid standards (1-40 or 1-42 amino acids)  
10       were prepared such that the final composition equaled 0.5 M guanidine in the presence of 0.1% bovine serum albumin (BSA).

          The total  $\beta$ -amyloid sandwich ELISA, quantitating both  $\beta$ -amyloid (aa 1-40) and  $\beta$ -amyloid (aa 1-42) consists of two monoclonal antibodies (mAb) to  $\beta$ -amyloid. The capture antibody, 266<sup>14</sup>, is specific to amino acids 13 - 28 of  $\beta$ -  
15       amyloid. The antibody 3D6<sup>15</sup>, which is specific to amino acids 1 - 5 of  $\beta$ -amyloid, is biotinylated and served as the reporter antibody in the assay. The 3D6 biotinylation procedure employs the manufacturer's (Pierce, Rockford IL) protocol for NHS-biotin labeling of immunoglobulins except that 100 mM sodium bicarbonate, pH 8.5 buffer is used. The 3D6 antibody does not  
20       recognize secreted amyloid precursor protein (APP) or full-length APP but detects only  $\beta$ -amyloid species with an amino terminal aspartic acid. The assay has a lower limit of sensitivity of ~50 pg/ml (11 pM) and shows no cross-reactivity to the endogenous murine  $\beta$ -amyloid peptide at concentrations up to 1 ng/ml.

25           The configuration of the sandwich ELISA quantitating the level of  $\beta$ -amyloid (aa 1-42) employs the mAb 21F12<sup>15</sup> (which recognizes amino acids 33-42 of  $\beta$ -amyloid) as the capture antibody. Biotinylated 3D6 is also the reporter

-- 377 --

antibody in this assay which has a lower limit of sensitivity of ~ 125 pg/ml (28 pM).

The 266 and 21F12 capture mAbs are coated at 10 µg/ml into 96 well immunoassay plates (Costar, Cambridge MA) overnight at room temperature.

5 The plates are then aspirated and blocked with 0.25% human serum albumin in PBS buffer for at least 1 hour at room temperature, then stored desiccated at 4°C until use. The plates are rehydrated with wash buffer (Tris-buffered saline, 0.05% Tween 20) prior to use. The samples and standards are added to the plates and incubated overnight at 4°C. The plates are washed ≥ 3 times

10 with wash buffer between each step of the assay. The biotinylated 3D6, diluted to 0.5 µg/ml in casein incubation buffer (0.25% casein, PBS, 0.05% Tween 20, pH 7.4) is incubated in the well for 1 hour at room temperature. Avidin-HRP (Vector, Burlingame CA) diluted 1:4000 in casein incubation buffer is added to the wells for 1 hour at room temperature. The colorimetric substrate, Slow

15 TMB-ELISA (Pierce, Cambridge MA), is added and allowed to react for 15 minutes, after which the enzymatic reaction is stopped with addition of 2 N H<sub>2</sub>SO<sub>4</sub>. Reaction product is quantified using a Molecular Devices Vmax (Molecular Devices, Menlo Park CA) measuring the difference in absorbance at 450 nm and 650 nm.

20 2. Blood Assay

The EDTA plasma is diluted 1:1 in specimen diluent (0.2 gm/l sodium phosphate•H<sub>2</sub>O (monobasic), 2.16 gm/l sodium phosphate•7H<sub>2</sub>O (dibasic), 0.5gm/l thimerosal, 8.5 gm/l sodium chloride, 0.5 ml TritonX-405, 6.0 g/l globulin-free bovine serum albumin; and water). The samples and standards in

25 specimen diluent are assayed using the total β-amyloid assay (266 capture/3D6 reporter) described above for the brain assay except the specimen diluent was used instead of the casein diluents described.

## Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:  
  
Although claims 1-31 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. ☒ Claims Nos.: 1-30,32-59,61-88(all partially)  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  
  
see FURTHER INFORMATION sheet PCT/ISA/210
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☒ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☒ No protest accompanied the payment of additional search fees.

## INTERNATIONAL SEARCH REPORT

International Application No. PCT/US 97/20804

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Claims Nos.: 1-30,32-59,61-88(all partially)

The scope of the claims 1-30, 32-59 and 61-88 is very broad and speculative. A formula consisting virtually of variables which are moreover in at least part of the claims ill-defined (e.g. the use of "(hetero)aryl" and "heterocyclicl") and from which formula many embodiments are disclaimed cannot be considered to be a clear and concise definition of patentable subject-matter (Art.6 PCT).

Furthermore the available experimental data actually only comprise a very small part of the compounds claimed, which part is moreover not evenly distributed over the whole claimed area. Therefore the claims can also not be considered to represent a permissible generalisation which is fairly based on experimental evidence, that is, they are also not adequately supported by the description (Art.6 PCT).

Therefore a meaningful and economically feasible search could not encompass the complete subject-matter of the claims. Consequently the search had been limited to the actually synthesised examples and (closely) related analogs, that is the compounds encompassed by the claim 89 and the related claims 31 and 60 and extended to compounds with the same activity (Art.17(2)(a)(ii) PCT, PCT Guidelines III,2.1)).
